# Empirically Investigating Structural Factors Facilitating Cartel: A Case of Japanese Manufacturing 

Yasushi Kudo* and Hiroyuki Odagiri**

April 2014

#### Abstract

This paper empirically investigates what kinds of structural factors such as demand or supply factors facilitate or hinder collusive practices in Japanese manufacturing industry using cartel cases which are discovered and prosecuted by Japan Fair Trade Commission (JFTC) over 1990-2004. Our analysis shows demand factors measured by growth rates of values of shipments and its fluctuations had statistiscally significant negative relations with cartels, and supply factors proxied by barriers to entry which are measured by monetary value of inventory per establishment had statistically signifcant negative relations with cartels. Market concentration, measured by Herfindahl-Hirschman Index (HHI) or 3-firm concentration ratio (CR3), had negative but insignificant relations with cartels. Our findings are similar to what Office of Fair Trading (2005) had reported except the results of growth rates of values of shipments and market concentration, which are opposite to our results.

Key Words: cartels, industry structure, emprical study, Japanese manufacturing industry

[^0]
## 1. Introduction

The stability of cartels has been extensively analyzed theoretically through the theory of repeated games since the 1970's (see Feuerstein (2005)). Those studies uncover what kinds of industry factors influences the stability of cartels, and thus what could make cartel unstable, and finaly leads them to collapse. Those factors are not only structural ones such as the number of competitors and barriers to entry, but also behaviroal ones such as types of goods (substitues or complements), the mode of competition in a industry (price or quantity competition), horizontal or vertical product differentiation when products are differentiated.

The purpose of this paper is to empirically investigate what kinds of structural factors of industries have been influensing illegal cartels via data on illegal cartels in Japanese manufacturing industies. ${ }^{1}$ Moreover, by employing results of an empirical analysis, we predict the the probability of cartel formation and empirically identify the characteristics of cartels occurred in Japan as well as the characteristics of the industries in which those businesses were involved. The data we use cover manufacturing industries in Japan and does not include data related to bid-rigging in the construction industry, which involves determining the winner of bids on public procurement. There are two reasons why we examined cartels in manufacturing industries. One reason is that the analysis related to bid-rigging in the construction industry in Japan has already been conducted as part of joint research at the Competition Policy Research Center (Yanagawa et al. (2005), Tanno et al. (2008), and Ishibashi et al. (2010)) and it would be sufficient to refer to those works. The other reason is that, as is detailed in Section 3, we were unable to obtain data on industry structures for non-manufacturing industries at the 3-digit industry level as classified according to Japanese Standard Industry Classification (hereafter, JSIC).

Furthermore, regarding an empirical analysis related to the probability of cartel formation, prior research by a competition authority exists in the form of research conducted by the U. K. Office of Fair Trading (OFT) (OFT (2005)). ${ }^{2}$

In order to empirically analyze factors leading to the formation and continuation of cartels as well as those for hindering cartels, and to conduct a statistical test for hypotheses on theoretical analysis of cartels, it is desireble to delve empirically into the relations between structural factors of industries identified in theoretical literatures on collusion and the formation and continuation of all cartels, not just prosecuted ones. However, because in general cartels operate in places not detectable by competition authorities, it would be impossible to learn about all cartels and thus this method would prove impossible without the use of the data related to legal cartels. As the analysis in this chapter uses data only for illegal cartels, the results of our analysis are limited in their scope. However, these results should be sufficient for allowing us

[^1]to ascertain the characteristics of industries in Japan in which cartels were formed. Furthermore, through a comparison with the results of the abovementioned OFT (2005), it is be possible to evaluate the differences between characteristics of European and Japanese industries.

The structure of this paper is as follows. In Section 2, we review empirical research related to the factors promoting the formation and continuation of cartels and factors involved in the prevention of cartels, as well as the length of existence of cartels and factors determining these time periods. Section 3 provides an explanation of the data used in this research. Section 4 explains the results of the empirical analysis and Section 5 concludes this paper.

## 2. Empirical studies concerning the formation and continuation of cartels

There have been a number of researches which investigates factors influencing the formation of cartels. A survey paper by Levenstein and Suslow (2006) covering this kind of researches serves as a reference, and Levenstein and Suslow (2014) intensively surveys empirics in the economic analysis of cartel. As mentioned in the previous section, performing an empirical analysis of structural factors influencing the formation of cartels requires data on all cartels, that is, hidden and uncovered cartels. However because cartel is not usually overt, we cannot do such study except when cartels are operated under legal approval by the goverment. Below are studies which used almost all the cartels including legal ones approved by the government: Symeonidis (2003) studies relationships between the number of cartels and the structures of industries, Suslow (2005) studies relationships between the length of cartel and the structures of industries, and Jacquemin et al. (1981) studies export cartels in Japan. Those researches are thought to cover all possible cartels that existed during the period of their analysis. Although the present paper only uses cartels data which actions by competition authority were taken, this research will uncovers relationships between cartels and the structures of industries in Japan, and by doing so it contributes to test theoretical hypotheses proposed in several theoretical papers.

Symeonidis (2003) applied data on the 1950's UK manufacturing industries (151 industries from the 4-digit category for UK industries) to conduct an empirical analysis of relationships between cartels and the characteristics of industry structures which are the degree of concentration, the growth rate of demand, capital intensity, research and development (R\&D), and so on. The study use samples of the 71 legal cartels formed under the 1956 UK Restrictive Trade Practices Law and 80 competitive industries. According to its result, while there was a high probability of cartels in industries with high capital intensity, cartels in advertising-intensive industries are unlikely to occur compared to less advertising-intensive industries. Regarding relationship with demand growth, the probability of cartels in industries with growing demand was higher than that of industries with stagnant or declining demand growth. Regarding relationship with market concentration, if it controls the endogeneity ${ }^{3}$ of the degree of concentration, the

[^2]result shows that an inverted $u$-shaped relationship between cartels and degree of concentration. However, when the effect of capital concentration is controled, we were unable to confirm clearly correlation between them. Concerning relationp to R\&D, it was observed that the likelihood of cartels in industries with high intensity in R\&D was lower than that of industries with low intensity in R\&D.

Suslow (2005) analyzed factors influencing the length of cartel operation via applying a survival analysis technique using 71 cartels in 45 industries over periods from 1920 to 1939, for which there were clear written agreements on collaboraton to limit its production and to raise its prices. According to the analysis, declines in industry production and fluctuations in the economy posed a significant burden in relation to the perpetuation of cartels. The length of cartels was found to have been extended in cases where contracts stipulated penalties for violating cartel rules. Furthermore, factors relating to the provision of patents and cross-licenses also significantly affected the perpetuation of cartels. Conversely, the length of cartels was significantly shortened in cases where the cartel handled a large number of products. Regarding the number of cartel participants (the number of countries or businesses participating cartels) and length of existence, the length of cartel reduced as the number of participants grew but this relationship was insignificant.

Jacquemin et al. (1981) constructed an economic model for the persistence of export cartels which were legalized by the Japanese government, and conducted an empirical analysis to seek what factors determined the length of periods of these cartels. The cartels examined by the above researches were ones which were prevalent after the depression in 1964 and 1965 from 1967 to the first oil shock in 1972. Their data include degree of market concentration, volume of production and volume of export from 40 industries (6-digit category defined by Ministry of International Trade and Industry and the 4-digit category defined in Japan Standard Industry Classification (JSIC)). Based on the data, the average persistence periods of the legal cartels were 10 years, the average degree of market concentration of industries with the legal cartels was $59.5 \%$, and that of all the manufacturing industries was $62.7 \%$. The average degree of concentration in the industries with the legal cartels was not significantly low from that of all the manufacturing industries. Their results show that the degree of market concentration has a negative impact on the persistence periods of the legal cartels, but it is insignificant. Theoretically speaking, as a greater number of firms which participates in a cartel increases, the cartel will become unstable. ${ }^{4}$ The authors give an interpretation for thre result that even when there are a large number of firms in a cartel, legalized cartels tend to maintain their stability. Regarding the relationship between cartels and the degree of product differentiation, the results show that it was easy for cartels to sustain when their products were of similar quality. Regarding the growth in demand, while it was not statistically significant, a high demand growth rate make the period of cartels shorter. As for types of cartels and its relationship to the persistence period, as the cases of cartels on prices and value of production in all the cartel cases increase, the persistence of the cartels decreases significantly. However, this effect declined in an absolute value for

[^3]cartels that were also involved in both international and domestic markets.

## 3. The Data

The target of the present paper was cartels (whch does not include bid-rigging in government procurement) in Japan manufacturing industries (Category F in JSIC) which "unfair restraint of trade" was ordered or which surcharge were assessed directly without such order between 1990 and 2004. This data includes discovered cartels only and thus it does not include cartels against which no government actions were taken. Thus, our cartel data is not a proper measure for all cartels which exist within these industries over the sample periods. Moreover, even in cases where a cartel was suspected, if the government was unable to act on those suspicions, then it was not recognized as a cartel and thus is not reflected in the data. That is, empirical results with the discovered cartels may also reflect the ability of the competition authority to capture cartels. Given these limitations on our data, special cares are required in interpreting results.

However, even when focusing only on cartels against which the government action was taken, this is sufficient for grasping the characteristics of Japanese industries in which cartels occur because we are able to delve into the relationship between cartels existing in Japan and the structural factors of industries in which cartels are recognized. Furthermore, given the fact that Jacquemin et al. (1981) is thought to be the only research to use data on cartels in Japan in analyzing the relationship between cartels and industry structures, we believe this study can provide empirics on the economic theory of cartels.

In this section, first we discuss the data for dependent variables and independent variables. Second, referring to the theoretical hypotheses intensively studied in economics so far, we summarize theoretical relationships between demand and supply factors and the formation of cartels.

## (1) Dependent variables

First, we explain dependent variables used in this study. The basis for dependent variables are cartels within Japan's manufacturing industries which "unfair trade restrictions" were ordered for or against which action penalties were assessed directly without such warning by the JFTC between 1990 and 2004. Following OFT (2005), we use the following three types of dependent variables. The first one is a binominal variable reflecting that if no cartel was confirmed during the sample periods, then it takes 0 , and 1 otherwise (that is, if a cartel was confirmed.). The second one is an ordered variable which states that if no cartel was confirme, then it takes 0 . If only a single cartel was confirmed, then it takes 1 , and if two or more cartels were confirmed, then it takes 2 . In addition to whether or not cartel is confirmed, the second variable also evaluates whether or not there were multiple instances of violations. The third one represents the actual number of cartels (including 0 cases) which occurred during the sample periods.

The 3-digit code category in JSIC lists 150 categories for manufacturers, and thus it is ideal to use all the 150 industries. However, in consideration of issues related to data availability, this analysis uses data from

131 industries. Among those, there were 35 cases of actions taken by JFTC. Table 1 indicates the industry classification code, number of cartels, and whether or not there is relevant data. Table 2-B provides summary statistics for the number of cartels. Looking at the intermediate classification (2-digit code), the industries with the highest number of confirmed cartels are the chemical industry (No. 17) and the ceramics, stone and clay products industry (No. 22), both with eight cartels. The steel industry (No. 23) follows them with four cartels (number of incidents based on calculations that do not include industries for which data was not available.). In the sub-category (3-digit code), the industries with the highest number of confirmed cartels were the oil and fat products, soaps, synthetic detergents, surface-active agents and paints industry (No. 175), the industrial organic chemicals industry (No. 173), and the copperware manufacturing industry (No. 221), each of which had three cartels. According to the OFT (2005), out of the 70 cartels (of which, 48 were manufacturing) against which action was taken by the EC between 1990 and 2004, and out of the 68 cartels (of which, 63 were manufacturing) against which action was taken by the U . S. Department of Justice (USDOJ) between 1994 and 2004, 11 and 14 cartels, respectively, were found in Manufacturer of Basic Chemicals. While a direct comparison is not possible because Japan does not use the same classification codes as EC or USDOJ, it can be seen that many cartels exist in the chemical industries among these three regions.
<Table 1 around here>
(2) Data used for independent variables

Next, we explain the data used for independent variables. Data used as independent variables are calculated by surveying all the establishments listed under "Industry Statistics" in the 1998 Industry Statistics Table of Manufucaturing Census published by the Ministry of Economy, Trade and Industry (METI). This census includes value of shipments, number of employees, number of establishments, value of product inventory, cash earnings, value of year-end fixed tangible assets, and acquisition value of machinery and equipment. This data is noted by industry based on the 3-digit class as defined by the JSIC. For data on the demand growth rate, we calculated the growth rate of value of shipments from 1995 and 1998. Furthermore, for demand fluctuations, first we calculated the growth rate of the value of shipments between the adjacent two years (for example 1990 and 1993) from 1990 to 2004, and then take the standard deviation of the computed growth rates of the value of shipments. As the index for the degree of industry concentration, we used the Herfindahl-Hirschman Index (HHI) in 6-digit level published under "Corporate Statistics" in the Industrial Statistics Table for 2002 and the sum of shares of the top 3 companies (CR3) to compute the weighted average of HHI and CR3 with the value of shipment at 3-digit level industries as weight. As proxy variables for barriers to entry, we use the inventory per establishment and the machinery/device acquisition value per establishment, which was computed by dividing the inventory and the machinery/device acquisition value by the number of establishemts, respectively. As a
proxy variable for supply capacity, we estimate the capacity utilization ratio (CUR) by the following method. First, for each industry, we select the largest value of shipments among annual value of shipments during the sample periods. Then, we divide the value of shipment at 1998 by that selected largest number to derive the CUR. For example, if the value of shipment at 1998 is the maximum value from 1990 to 2004, then the CUR is 1.0. And if the value is 1,000 billion yen at 1998 and the highest value is 2,000 billion yen at 1995 , then the CUR is $0.5(1,000 / 2,000)$.

The summary statistics for the independent variable is given in Table 2-A, and for the dependent variables is given in Table 2-B. Table 3 shows coefficients of correlation between the independent variables. For the average of values of industry concentration, HHI is approximately 1,150 and CR3 is approximately $40 \%$. The percentage ratios of acquisitions of machinery and equipment and product inventory to the value of shipments were about $3 \%$ and $5 \%$, respectively. The estimated value of CUR is approximately $85 \%$ on average. The standard deviation for each independent variable indicates the degree of fluctuation for the variables, but as this meausrement for fluctuation is subject to unit measurement of variables, it is difficult to compare the fluctuations among variables with standard deviation. Therefore, a comparison of the fluctuation among variables is conducted via the coefficient of variation, which is computed by dividing the standard deviation by the average value and defined only for variables with positive mean. For earnings and machinery/equipment acquisition costs, we use the per-establishment value and the per-employee value of those. Comparing the per-establishment value and the per-employee value, we see that the degree of fluctuation is greater for the per-establishment values. Also, for the fluctuations of variables base on monetary amount and variables based on the percetage value over shipments, the former is more fluctuated than the latter.

Theoretical studies on cartels show that, in addition to structural factors such as the number of companies in an industry, behavioral factors such as the mode of competition (price or quantity) and the degree of product differentiation are also important. However, because we were unable to obtain variables that measure such behavioral factors (for example, the ratio of advertisement expenditures to sales has been conventionally used for "the degree of product differentiation"), we are unable to estimate the effect of behavioral factors on cartel formation. An empirical analysis of cartel formation with taking into account behavioral factors is for future research.
$<$ Table 2 around here>
$<$ Table 3 around here $>$
(3) Theoretical hypotheses on the effect of demand and supply on cartel

This section summarizes the theoretical hypotheses in economics literature to evaluate that demand and supply factors are expected to have positve or negative impacts on cartels.

First we consider the relationship between cartel formation and demand factors. When the growth rate of the value of shipments is positive, the revenue is expected to increase in the future. In such a case, firms will be preferred to form a cartel rather than to compete because profits are expected to increase in the future with all the other things being held constant. Therefore, there will be a positive relationship between the demand growth and cartel formation. As for the fluctuation in the growth rate of the value of shipments, the greater the fluctuation becomes, the greater the level of market demand uncertainty will become. However, the occurrence of uncertainty implies that future profits will also become uncertain and thus firms will be preferred to break the cartel and try to make money in short run rather to stay in the cartel. Therefore, when uncertainy in future demand increases, cartels will destabilize. This means that demand fluctuations and cartel formation are thought to have a negative correlation. Thus, in summarizing the evaluation of demand factors, it is hypothesized that the growth rate of the value of shipments has a positive relation, while fluctuations in the same growth rate has a negative relation, with cartels.

Next, we consider the relationship between cartels and supply factors such as industry concentration and entry barriers. A larger number of cartel companies make it difficult to maintain the cartel, and, conversely, a smaller number of companies are thought to make it easier to sustain a cartel. Because of the relationship that when there are a large number of companies, the level of market concentration decreases and conversely the level of market concentration increases when there are fewer companies, there will be a positive relation between the degree of indusry concentration and cartel formation. As for entry barriers, when this is high, the number of existing companies is lower and new entries cannot be expected. Therefore, similarly to industry concentration, there will be positive relation between entry barriers and cartel formation. In this analysis, we used HHI and CR3 as measures of the degree of industry concentration, and inventory of products per establishment and machinery/equipment acquisition value per establishment as proxy variables for entry barriers. Both variables are thought to have a positive sigen.

For other variables, particularly those related to employment, we will discuss our interpretations of the effect of machinery/equipment acquisition costs per employee, the value of shipments which is used to control the effect of industry size, the value of shipments per establishemt, and the several ratios on cartel formation as we obtain our estimates.

## 4. Results of estimating the Effect to faciliate or hinder collusion

This section explains results of estimation of industry structural factors influencing whether or not cartels exist, whether or not cartels occur only once or more, and the number of cartels. For each analysis, we estimate three different models in total: the basic model, the CUR model in which the CUR is added to the basic model, and the ratio model in which various ratios (tangible fixed asset ratio, cash earnings ratio, machinery/equipment ratio, and product inventory ratio) are added to control industry scale effects. ${ }^{5}$ The

[^4]independent variables used for the basic model are the value of shipments, the value of shipments per establishment, cash earnings per employee or per establishment, inventory per establishment, the growth rate of the value of shipments and its fluctuations measured by its standard deviation, machinery/equipment acquisition value per employee and per establishment.
(1) Results of estimation of the model for the cartel formation

Regarding the relationship between the existence of cartels and structural factors, we conduct a binary logit model (BLM) that assigns the binary values as dependent variables explained in Section 2. We estimated three types of models (the basic, the CUR and the ratio models) but obtained similar results. We conducted Wald tests where the basic model is the null hypothesis and the other two models were alternate hypotheses, and the null hypothesis is not rejected. Therefore, basically we focus on the result of the basic model below. The BLM results are summarized in Table 4.
$<$ Table 4 around here $>$

The results show that as the value of shipments grows, the likelihood of cartel formation also grows and also that the larger the size of an industry is, the greater the likelihood of occurences of cartels. However, considering the fact that the basis for our dependent variable is cartels which were captured by JFTC, the following interpretation is also possible. That is, because it is expected that the greater the size of an industry is, the greater the damage afflicted by a cartel on the overall economy is expected, competition authorities put their more resources in investigating large-scale industries.

Both of the two demand factors in our model (the growth rate of the value of shipments and its fluctuations) are confirmed to have a significantly negative effect on the formation of cartels. This result is the same for the basic model, the CUR model, and the ratio model, and we see that fluctuations in the growth rate of the value of shipments support a theoretical hypothesis. In other words, this means that in industry with unstable demand and uncerain economic environment cartels will become more difficult to form (or collapse easily). Conversely, the result that the growth rate of the value of shipments has a negative impact on cartel formation does not support a theoretical hypothesis. The negative sign means that cartels are easier to form when demand is on the decline. One interpretation of this result is that in a state of declining demand, companies seek to secure a certain level of profits through, for example, the formation of cartels instead of competing for their survival. This might be the reason for the negative relationship between the growth rate of the value of shipments and cartel formation.

Similarly, for the inventory value per establishment and the machinery/equipment acquisition value per establishment used as proxy variables for entry barriers, there is a positive relationship between these two variables and the formation of cartels, and thus this supports a theoretical hypothesis which states high entry barriers will facilitate collusion. We empirically confirmed that a higher degree of entry barriers
make it more difficult for new competitors to enter a market which can be a pressure on cartels.
Contrary to the predictions of the theoretical hypothesis on the relationship between industry concentration and cartel formation, our result shows for both CR3 and HHI as industry concentration increase, the likelihood of cartel formation decreased, although it is not statistically significant. This result differs from that of OFT (2005). The following two interpretations can be infered from our results: the first one is that, as is often found in classical industrial organization literature, it is implied that industries with a high level of industry concentration also have a high profit rates. Therefore, there is no need to form cartels in idustry with high concentration and thus there is no relationship between them. Another interpretation is that given the fact that this analysis uses data only for cartels which are captured by JFTC, in concentrated industries firms successfully form cartels and it is difficult for JFTC to correctly capture them.

With cash earnings per employee, which is a factor related to employee, the results showed a significant positive correlation, which is the same as OFT (2005). Factors concerning employee in relation to cartels were not indicated in the theoretical analysis but OFT makes the following two indications for these results. The first is that in industries with high cash earnings per employee there are thought to be employees with higher wages but these employees are thought to be in roles related to vital information concerning a company's business. As a result, there is a higher possibility of a cartel being discovered or of discovering proof related to a cartel. The second is the possibility that this variable reflects effects of other variables not included in the model. ${ }^{6}$ As a separate interpretation differing from that of OFT, similar to the relationship between the value of shipments and the formation of cartels, there is a possibility that the investigations into cartels by competition authorities tend to focus on high profit industries. Conversely, the opposite view is also possible. That is, because of cartels, company can make high profits and thus, as a result, employees can obtain high cash earnings.

Regarding the machinery/equipment acquisition value per employee, the results indicated a significantly negative relationship. It is difficult to interpret how this variable impacts cartel formation, but we do offer an interpretation based on viewing machinery/equipment acquisition value per employee as a capital labor ratio per employee. Labor productivity is expected to increase as the capital labor ratio increases. The increase in labor productivity is a factor that potentially increases overall corporate profitability and, as a result, high in capital labor ratio could decrease the likelihood of cartel formation.

Regarding other variables, results showed that the relationship between cash earnings per establishment and cartel formation is negative and that CUR and cartel formation is positive. An interpretation of these correlations will be left for future discussions.

Lastly, referring to the pseudo $\mathrm{R}^{2}$, the logit model of the present paper explains approximately $22 \%$ to $26 \%$ of the factors related to cartel formation.

[^5](2) Results of estimation of the model for the multiple cartel formation

Next, in addition to whether or not cartels exist, we apply ordered logit model (OLM) to analyze whether or not there were multiple cartel cases. Table 5 summarizes the results of estimating the model. When comparing the OLM results to the BLM results, allmost all of the results on signs of coefficient, estimated magnitudes of coefficient and those significance were not different each other, except for the machinery/equipment acquisition value per establishment. Therefore, the interpretations provided in the results of BLM are applicable to interpreting the results of OLM.

However, it should be paid attention to interpretation of results concerning signs of coefficients, positive or negative. In the BLM, the dependent variable is whether or not a cartel exists and it takes either 0 or 1 . If the sign of a certain independent variable is positive, then it can be interpreted to have a positive impact on a cartel formation because it increases the probability that a cartel will be formed. Conversely, because a dependent variable takes 0,1 , or 2 in the OLM, it is not always the case that an independent variable with the positive estimated coefficients increases probability that a cartel will be formed once or more. Therefore, judging the effects of factors related to the formation of cartels in the OLM requires computation of partial derivatives to evaluate the marginal effect of factors on cartel cases. That is, for each of values of the dependent variable 0,1 , or 2 , we need to evaluate the partial derivatives of independent variables.

Table 6 summarizes marginal effects of independent variables (industrial factors) on the probability of cartel formation. As the marginal effects vary depending on values which each independent variable takes, in this study the marginal effects were evaluated at mean values of industrial factors. According to calculations of the effects, we see that industrial factors with a positive sign in the OLM (value of shipments, earnings per employee, inventory per establishment and machinery/equipment acquisition value per establishment) contribute to decrease the probability of non cartel, and to increase the probability that cartel occurs one time only or on multiple occasions. Similarly, factors with a negative sign in the OLM (the growth rate in value of shipments and its fluctuations) leads to increase in probability of non cartel, and to decrease in the probability that cartel activities occur one time only or on multiple occasions. ${ }^{7}$
$<$ Tables 5-6 around here $>$
(3) Results of estimation of the model for the frequency of cartel

The above involves analyses of the effect of each factor on the probability of cartel formation. Next, we apply a Negative Binominal Model (NBM) to analyze the relationship between industrial factors and frequencies of cartel activities. The dependent variable in the NBM is the number of cartel formations,

[^6]which takes 0 or a positive integer. In the study by OFT, they use the ordinary least squares estimator. However, in this study we use the NBM because the dependent variable takes positive integers, not a continuous dependent variable, and therefore the NBM is better than the OLS. ${ }^{8}$

The NMB estimate results are summarized in Table 7. ${ }^{9}$ Regarding the effect of each factor on the number of times a cartel is formed, the results for signs of coefficients were the same as ones in the BLM, but statistical significances are different. For example, in regards to the influence of demand factors (the growth rate of value of shipments and its fluctuations) on the formation of cartels, as with the results obtained in the BLM, fluctuations in the growth rate of value of shipments had significant negative effects on cartel occurences, but the growth rate of value of shipments is negative but not significant. In other words, while the growth rate of value of shipments can be seen as a significant factor in explaining whether or not cartels exist, it does not stand as a significant factor in explaining the number of cartel occurences.

As proxy variables for barriers to entry, we use the inventory per establishment and machinery/equipment per establishment. The former has a significant positive effect on the number of cartel cases, while the latter also has a positive effect but it is not significant. Furthermore, wthe machinery/equipment acquisition value per employee has a negative effect as in the BLM, but this is not significant in the NBM. Conversely, market concentration (CR3) is not significant in either the BLM or the OLM but it is a significant negative effect in the NBM. Similar to the BLM and OLM, the earnings per employee has a significantly positive effect on the frequency of cartel occurences, but cash earnings per establishment has a significantly negative effect.

## $<$ Table 7 around here $>$

(4) Predictions on the probability of cartel and the number of cartel occurences

Using the estimates obtained in the series of three estimation explaind so far, we predict the probability of cartel formation, the probability whether or not multiple cartels exist, and the number of cartel occurences.

Column 3 in Table 8 through Table 10 summarizes the number of discovered cartel cases which the JFTC took action during the sample period (1990-2004) while column 4 and beyond respectively summarize the results of BLM-based predictions for the probability of cartels (hereafter "predicted cartel formation probability"), the results of OLM-based predictions for the probability of 0,1 , or 2 cartels (hereafter "predicted probability of multiple cartels"), and NBM-based predictions for the number of cartel

[^7]occurences (hereafter "predicted number of cartel cases"). We estimated three different equations (the basic, the CUR and the ratio models) in each of the BLM, the OLM, and the NBM, where equations have different independent variables within each estimation technique. Therefore, for each model we calculated the predicted values for the cartel formation probability, the probability of multiple cartels, and the number of cartel cases (Table 8 summarizes the basic model, Table 9 summarize the CUR model and Table 10 summarizes the ratio model).
We calculated correlation coefficients of the predicted values for cartel formation probability, probability of multiple cartels, and the number of incidents among the three equations, all three types of predictions returned a high correlation coefficient of 0.9 or higher, which Table 16 summarizes. Thus it is judged that similar prediction values would be gained regardless of the model used. Overall, the predicted values are not significantly influenced by the selection of independent variables.
$<$ Table 8-10 around here >

However, because predicted values for individual industries are thought to be influenced by selection of independent variables, we first looked at the predicted values of the cartel formation probability and for each model we selected the 40 industries with the highest probability and then picked the top 40 industries in all models. Table 11 summarizes such selected 32 industries which ranked within 40 industries in all models. Cartels were captured in 22 industries out of total 131 industries, and of these 13 industries ranked in the top 40 . The industry with the highest predicted cartel formation probability is MOTOR VEHICLES, PARTS AND ACCESSORIES (JPSIC 301), for which one cartel case is found during the sample period. The second highest predicted probability is for FABRICATED CONSTRUCTIONAL AND ARCHITECTURAL METAL PRODUCTS (JPSIC 254), which also had one case during the sample period, and the $3^{\text {rd }}$ highest is ROLLING OF NON-FERROUS METALS AND ALLOYS, INCLUDING DRAWING AND EXTRUDING (JPSIC 243). Conversely, there were industries against which action is taken but still had a low predicted probability. For example, in LIVESTOCK PRODUCTS (JPSIC 91) and CANNED AND PRESERVED FRUIT AND VEGETABLE PRODUCTS (JPSIC 93) industries there is one cartel discovered by the JFTC during the sample period but these predicted probability is low. The reason for this low probability is that there could be other industry factors not augmented in the regression equations, and further research for the factor is required.

While Table 11 provides the predicted cartel formation probability ranked in top 40 in all the models regardless of whether or not a cartel is confirmed in industry, in Table 12 we focused specifically on 109 industries for which no cartels were confirmed during the sample period and used the same methods to select 33 industries from among the 40 industries with the highest predicted probability. Of these, both HOUSEHOLD ELECTRIC APPLIANCES (JPSIC 272) and ELECTRICAL GENERATING, TRANSMISSION, DISTRIBUTION AND INDUSTRIAL APPARATUS (JPSIC 271) are ranked in the top

10 for Table 11 as well.
$<$ Table 11-12 around here $>$

Next, we evaluate the predicted number of cartel cases. Table 13 provides it for all industries and Table 14 summarizes the industries with the predicted numbers in order of the highest predicted cartel probability based on the BLM basic model. Based on the predictions with NBM basic model, the predicted number of cartel cases for each of the top three industries, MOTOR VEHICLES, PARTS AND ACCESSORIES, FABRICATED CONSTRUCTIONAL AND ARCHITECTURAL METAL PRODUCTS, and ROLLING OF NON-FERROUS METALS AND ALLOYS, is 1.7, 1.2 and 1.4 incidents, respectively. As each industry has one cartel, there is no significant divergence between the prediction and the actual number of cartel. However, for industries in which cartel were confirmed but had a low predicted cartel formation probability, the predicted number of cartels is significantly low compared to the actual number of cartels. For example, FERROUS METAL MACHINE PARTS AND TOOLING PRODUCTS (JPSIC 235) and OIL AND FAT PRODUCTS, SOAPS, SYNTHETIC DETERGENTS, SURFACE-ACTIVE AGENTS AND PAINTS (JPSIC 175) have two and five cartels, respectively, these predicted numbers is approximately 0.4 .

Table 15 provides the predicted the number of cartels in industries which no cartels are captured by the JFTC during the sample periodzero ordered from highest to lowest predicted cartel formation probability by the basic BLM. Regardless of which NBM model is applied, there are many industries with a value of less than 1.0 for the predicted number but looking at the mean value for all the three models, the industries with the highest number are CHEMICAL FERTILIZERS, SUGAR PROCESSING, and HOUSEHOLD ELECTRIC APPLIANCES.

However, as typical in the cross section analysis ${ }^{10}$, the pseud- $R^{2}$ value for these regression results is low and thus it is implied that factors besides the structural factors, such as advertising and/or research and development activites and behavioral factors, of industries used in this analysis could have significant influences.
$<$ Table 13-16 around here $>$

## 5. Conclusion

In this paper, we use data on Japanense manufacturing industries to conduct an empirical analysis for the relationship between structural factors of industries and cartel formation. Because we are unable to collect the total number of cartels (both overt and hidden) in manufacturing industries, our data

[^8]cover only for cartels against which legal is taken, and therefore there are some limitation on the scope of our analytical results. However, we identified characteristics of the structural factors of industries in which cartels are confirmed in Japanese industries.

First, regarding the relationship between the demand factors and cartel formation, we found that the growth rate of value of shipments and its fluctuations had a statistically significant negative effect and that while the former did not support the theoretical hypothesis, the latter support the hypothesis. Next, regarding the relationship between the supply factors and cartel formation, although market concentration does not have a statistically significant effect, contrary to the theoretical hypothesis, it has a negative relationship with cartel formation. The barriers to entry has a significant positive relationship with cartel formation, and this result implise that higher entry barriers results in an environment that made the formation of cartels easier and supports the theoretical hypothesis.

In comparing our results to the results of OFT (2005), it can be said that the fluctuations in the growth rate of value of shipments (demand side factor) and entry barriers (supply side factor) share an equivalent relationship with cartel formation. Conversely, the growth rate of value of shipments (demand side factor) and market concentration (supply side factor) have a reverse effect on cartel formation and our results do not support the theoretical hypothesis. The former is statistically significant, but the latter is not.

In addition to the above mentioned demand and supply factors, following OFT (2005), we analyze the relationship between employment factors and cartel formation. As a result, similar to the results in the OFT, earnings per employee has a significantly positive relationship with cartel formation.

In addition to empirical analysis for the test of theoretical hypotheses of economic theory of collusion, we also predicted several values with these estimation results as the basis for the cartel formation probability of each industry and the number of cartels, and then summarized the 30 industries with the highest probabilities. From the results, seven industries with actually confirmed cartels appear in the top 10 industries. Conversely, due to the inability to use certain data it is possible that there are factors not addressed in this analysis and there were industries with a low cartel formation probability despite the fact that cartels are captured. We also made predictions related to the number of cartels using the same methods but due to the same reasons as with the probability predictions, there were some industries with a significant divergence between the actual number of cases and its predictions

Next, we would like to discuss the policy implications derived from this analysis. These results can be used as an indicator for the discovery or selection of industries in which it is thought cartels are being formed. Among the various possible industries, when determining toward which industries competition authorities should focus the allocation of resources, it would be more efficient to allocate greater resources toward the monitoring of industries with demadn or supply factors (or both) observed as having a significant relationship to cartel formation. ${ }^{11}$

[^9]Having noted the above, we would like to state three limitations in this analysis. The first is that, as noted several times previously, this analysis focuses only on industries against which legal action is taken by the competition authority. The second is that the relationships between cartels and structural factors of industries used in this analysis are related to the manufacturing industries, and we do not focus on the characteristics of non-manufacturing industries due to data availability. We should hope for future analyses that incorporate data for non-manufacturing industries. The third is the other industrial factors such as advertising, research and development and behavioral factors are not included in this analysis observed by the estimated pseudo $\mathrm{R}^{2}$ value. Of the factors influencing cartels, the structural factors used in this analysis explained approximately $22 \%$. Considering this analysis is a cross-sectional analysis, this is not necessarily a low value. ${ }^{12}$ As indicated by the theoretical literature for collusion and confirmed empirically by this research, the structural factors are vital to cartel formation. Conversely, there is thought to be a significant dependence on other factors and, in particular, as noted in Section 2, the theoretical literature tells us that the quality of goods (substitutes or complements), the type of competition within an industry (price or quantity competition), product differenciation (horizontal or vertical product distinction) can affect cartel formation. By conducting an analysis that incorporates these other factors, it will be possible to empirically examine the relationship between cartels and those factors in greater detail.

Finally, the data used in this analysis is from cartels between 1990 and 2004, but in 2005 the leniency program is enacted in the Japan that reduces surcharge. Until today, because many firms use this system, the number of cartels captured has been increasing. Using the updated data on cartels since the enactment of this system to examine the influence of the system and reconfirming the relationship to structural factors of industries, we look forward to future research that clarifies the relationship between cartel formation and factors not explored in this research.

Note) Classification based on $11^{\text {th }}$ revision of Japan Standard Industrial Classification (March 2002). Number of cartels cases is the sum from 1990 to 2004. There are 150 industries in 4 -digit classification but the 18 industries with an "x" in the "Yes/No" column are not used in this analysis because continuity was lost with the revisions to the classification method and because for the tobacco industry, the exclusive manufacture of tobacco by JT is authorized.

Note) The dependent variable is an ordinal variable that applies 0 for no cartels, 1 for cartels, and 2 for two or more cartels. The value within the parentheses in the r value and ${ }^{*}$, ${ }^{* *}$, and ${ }^{* * *}$ indicate $10 \%, 5 \%$, and $1 \%$ respectively, all of which are statistically significant. The tangible fixed asset ratio, cash earnings ratio, machinery/equipment ratio, and product inventory ratio are respectively tang ible fixed assets, cash earnings, machinery/equipment acquisition value, and product inventory value divided by the value of shipments. The cut 1 and cut 2 constants represent the estimated $\tau_{2}$ and $\tau_{z}$ values for in this supplemental argument of this paper. For the Wald test statistic, refer to the Notes in Table 4.

Note) The columns following the first and second columns indicate the values for each model and its dependent variable. For example, the Basic 0 column includes the marginal value for each variable when the dependent variable is assigned the value 0 in the basic model. The value within the parentheses in the r value and *, **, and $* * *$ indicate $10 \%$, $5 \%$, and $1 \%$ respectively, all of which are statistically significant. The tangible fixed asset ratio, cash earnings ratio, machinery/equipment ratio, and product inventory ratio are respectively tangible fixed assets, cash earnings, machinery/equipment acquisition value, and product inventory value divided by the value of shipments.

Note) The dependent variable is the number of cartels. The value within the parentheses in the r value and $*, * *$, and $* * *$ ind icate $10 \%, 5 \%$, and $1 \%$ respectively, all of which are statistically significant. The tangible fixed asset ratio, cash earnings ratio, machinery/equipment ratio, and product inventory ratio are respectively tangible fixed assets, cash earnings, machinery/equipment acquisition value, pnd pro duct inventory value divided by the value of shipments. The overdispersion test row indicates the test statistic related to the test ( $\chi^{2}$ test) where the Poisson regression model is the null hypothesis and NBM is the alternate hypothesis. For the Wald test statistic, refer to the Notes in Table 4.

| Capacity utilization ratio model | 0.957 |  | 1.000 |
| Ratio model | 0.910 | 0.949 | 1.000 |

Note) Summarizes the correlation coefficients for expectancy value gained from the BLM, OLM, and NBM models. For example, the correlation coefficient for the expectancy value gained from the BLM basic and operating models was 0.961 and the correlation coefficient for the expectancy value gained from the basic and ratio models was 0.915 . OLM ( x ) indicates the expectancy value when the dependent variable value is x in the OLM. For example, for the probability expectancy rate for two or more cartels in the OLM, the expectancy value correlation coefficient gained from the basic model and Capacity utilization ratio model was 0.954 and, similarly, the expectancy value correlation coefficient gained from the basic model and ratio model was 0.904 .

## Appendix

This appendix explains that structural factors with positive coefficient ( $\beta_{k}$ ) do not necessarily increase the probability of $y=0,1$, or 2 . The marginal effect of independent variables in the OLM depends on with which values of those variables we evaluate. Let $\operatorname{Pr}(),. F($.$) and f($.$) denote$ probability, probability distribution function, and probability density function, $y$ denote the dependent variable, $\mathbf{x}$ denote a vector of independent variables, $\boldsymbol{\beta}$ denote a vector of coefficients, and $x_{k}$ and $\beta_{k}$ represent the $k$-th element of those vectors, respectively. Furthermore, $\tau_{i}(i=0,1,2)$ denotes the threshold values in the OLM. Without loss of generality, $\tau_{i}$ 's is ordered in $\tau_{2}>\tau_{1}>\tau_{0}=0$.

By formulation of the OLM, the probabilities when $y$ is 0,1 , or 2 are given by:

$$
\begin{align*}
& \operatorname{Pr}(y=0 \mid \mathbf{x})=F\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)  \tag{A.1}\\
& \operatorname{Pr}(y=1 \mid \mathbf{x})=F\left(\tau_{1}-\mathbf{x} \boldsymbol{\beta}\right)-F\left(\tau_{0}-\mathbf{x} \mathbf{B}\right), \text { and }  \tag{A.2}\\
& \operatorname{Pr}(y=2 \mid \mathbf{x})=1-F\left(\tau_{2}-\mathbf{x} \boldsymbol{\beta}\right) . \tag{A.3}
\end{align*}
$$

Next, taking the partial derivative of these probabilities with respect to $x_{k}$ will give marginal effects of $x_{k}$ on those probabilities:

$$
\begin{align*}
& \begin{aligned}
& \frac{\partial \operatorname{Pr}(y=0 \mid \mathbf{x})}{\partial x_{k}}=\frac{\partial F\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)}{\partial x_{k}}=-\beta_{k} f\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right) \\
& \begin{aligned}
\frac{\partial \operatorname{Pr}(y=1 \mid \mathbf{x})}{\partial x_{k}} & =\frac{\partial F\left(\tau_{1}-\mathbf{x} \boldsymbol{\beta}\right)}{\partial x_{k}}-\frac{\partial F\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)}{\partial x_{k}} \\
& =\beta_{k} f\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)-\beta_{k} f\left(\tau_{1}-\mathbf{x} \boldsymbol{\beta}\right) \\
& =\beta_{k}\left[f\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)-f\left(\tau_{1}-\mathbf{x} \boldsymbol{\beta}\right)\right], \text { and } \\
\frac{\partial \operatorname{Pr}(y=2 \mid \mathbf{x})}{\partial x_{k}} & =-\frac{\partial F\left(\tau_{2}-\mathbf{x} \boldsymbol{\beta}\right)}{\partial x_{k}}=\beta_{k} f\left(\tau_{2}-\mathbf{x} \boldsymbol{\beta}\right)
\end{aligned}
\end{aligned} . \tag{A.4}
\end{align*}
$$

Note that the probability density function $\mathrm{f}($.$) is always positive by its definition.$
Now, because the last term of (A.4) has a negative, the marginal effect with $y=0$ is the opposite to the sign of the coefficient $\beta_{k}$, which is to be estimated. That is, if our estimate for $\beta_{k}$ is positive, its structural factor has a negative marginal impact on the probability with $y=0$, and thus reduces the probability, and vice versa. For $y=1$, with equation (A.5), even when $\beta_{k}$ is a positive, if $f\left(\tau_{0}-\mathbf{x} \boldsymbol{\beta}\right)-$ $f\left(\tau_{1}-\mathbf{x} \boldsymbol{\beta}\right)$ is negative, then the marginal effect of $\mathrm{x}_{\mathrm{k}}$ is negative, and thus it reduces the probability with $y=0$, and vice versa. For $y=2$, contrary to cases of $y=0$, the equation (A.6) indicates that the structural factors with positive $\beta_{k}$ increase the probability of $y=2$, and vice versa.

The above discussion can be summarized as follows. The structural factors in industries with the estimated coefficient with positive sign increase the probability of cartels with two or more cases, but decrease the probability of non-cartels. Conversely, the structural factors with the estimated coefficient with negative sign increase the probability of non-cartels, but decrease the probability of cartels with two
or more cases. The marginal effect of a structural factor in industries on the probability of cartel with one case is dependent upon the values of the other independent variables.

[^1]:    ${ }^{1}$ By illegal cartels, we mean cases of price fixing or quantity agreement in which it was deemed an "unfair trade restriction" by Japan Fair Trade Commission and it resulted in a cease and desist order or a direct surcharge was assessed without the order.
    ${ }^{2}$ OFT research first calculated the correlation coefficient for the cartels in each industry against which action was taken by the EC or the USDOJ and then evaluated whether or not action against cartels had been taken in similar industries (correlation coefficient was 0.678 ). Next, they created a dependent variable based on the number of EC cartels and set the UK industry structural data as the independent variable to conduct a statistical analysis into the correlation between cartels and industrial structure.

[^2]:    ${ }^{3}$ Refers to an environment with the mutual correlation where concentration not only influences cartel formation, but also cartel formation influences concentration.

[^3]:    ${ }^{4}$ See Motta (2003), pp. 159-162.

[^4]:    ${ }^{5}$ This research uses different estimation methods for each of the three types of dependent variables. For details on each estimation method, readers are referred to Greene (2003), Chapter 21.

[^5]:    ${ }^{6}$ For example, OFT (2005) indicates a plus correlation coefficient between concentration and per employee wages. This research also indicates the comparatively high value of 0.5 for the correlation coefficient of both factors (Table 3). Considering these indications we excluded per employee wages and per establishment wages, which are independent variables related to wages, and conducted estimates but qualitatively speaking we reached similar results (In other words, the same symbol was estimated. Conversely, some variables lost their significance and the pseudo $\mathrm{R}^{2}$ value also declined by nearly 0.07 .).

[^6]:    ${ }^{7}$ Refer to the appendix for the marginal effect the independent variable in the OLM has on the probability for each number. For a detailed explanation, refer to, for example, Greene (2003) pp. 736-740.

[^7]:    ${ }^{8}$ As seen in B of Table 1 and Table 2, the dependent variables used in this research included many cases of 0 . As such, we could also consider estimates conducted using a Zero-Inflated Poisson model or a Zero-Inflated Negative Binominal model. We also conducted estimates using these models but many variables lost their significance and thus these methods were not considered optimal. As such, a binominal model was used for this research.
    ${ }^{9}$ Similar to with the BLM and OLM models, in the NBM as well the basic model was set as the regression hypothesis and the other two models were set as the alternate hypotheses to conduct a Wald test but as we could not discard the regression hypothesis, below we explain the estimate results for the basic model.

[^8]:    ${ }^{10}$ It is the analysis of different companies and industries at the same point in time. Time series analysis is to select individual companies or corporations and analyze chronological changes in the selected entity.

[^9]:    ${ }^{11}$ Porter (2005) and Harrington (2008) are survey papers on the detection of bid-rigging and cartels from data obtained as a result of the behavior of individual companies, including bid data for public procurement and chronological data on prices.
